

# Assignment 7

Contributor: Ngo Thanh Trung - 1677469

## 1. Employee class

### 1. Employee Class

Create a class called Employee that includes three instance variables—a first name (type String), a last name (type String) and a monthly salary (double). Provide a constructor that initializes the three instance variables. Provide a set and a get method for each instance variable. If the monthly salary is not positive, do not set its value. Write a test application named EmployeeTest that demonstrates class Employee's capabilities. Create two Employee objects and display each object's yearly salary. Then give each Employee a 10% raise and display each Employee's yearly salary again

Figure 1: Problem 1 Task Requirement

```
1 public class Employee {
2     private String firstName;
3     private String lastname;
4     private double monthySalary;
5
6     public Employee(String firstName, String lastname, double monthySalary) {
7         this.firstName = firstName;
8         this.lastname = lastname;
9         if (monthySalary >= 0) {
10             this.monthySalary = monthySalary;
11         } else {
12             this.monthySalary = 0.0;
13         }
14     }
15
16     public String getFirstName() {
17         return firstName;
18     }
19     public String getLastName() {
20         return lastname;
21     }
22     public double getMonthySalary() {
23         return monthySalary;
24     }
25     public void setFirstName(String firstName) {
26         this.firstName = firstName;
27     }
28     public void setLastname(String lastname) {
29         this.lastname = lastname;
30     }
31     public void setMonthySalary(double monthySalary) {
32         if (monthySalary >= 0) {
33             this.monthySalary = monthySalary;
34         }
35     }
36     public double getYearlySalary() {
37         // yearly bonus
38         return monthySalary * 13;
39     }
}
```

```

40     public void giveRaise(double raisePercentage) {
41         this.monthlySalary += monthlySalary * raisePercentage / 100;
42     }
43 }

45 public class EmployeeTest {
46     public static void main(String[] args) {
47         Employee emp1101 = new Employee("Nguyen", "A", 90);
48         Employee emp1100 = new Employee("Dao", "B", 1000);

50         System.out.println("Salary of " + emp1101.getFirstName() + " " + emp1101.
            getLastName() + ": " + emp1101.getMonthlySalary());
51         System.out.println("Salary of " + emp1100.getFirstName() + " " + emp1100.
            getLastName() + ": " + emp1100.getMonthlySalary());

53         // give each employee a 10% raise
54         emp1101.giveRaise(10);
55         emp1100.giveRaise(10);

57         emp1100.setMonthlySalary(-90);
58         emp1100.setFirstName("Tien");
59         emp1101.setLastname("T");

61         System.out.println("Salary of " + emp1101.getFirstName() + " " + emp1101.
            getLastName() + " after 10% raise: " + emp1101.getMonthlySalary());
62         System.out.println("Salary of " + emp1100.getFirstName() + " " + emp1100.
            getLastName() + " after 10% raise: " + emp1100.getMonthlySalary());

64         // display yearly salary after the raise
65         System.out.println("Yearly salary of " + emp1101.getFirstName() + " " +
            emp1101.getLastName() + " after 10% raise: " + emp1101.getYearlySalary
            ());
66         System.out.println("Yearly salary of " + emp1100.getFirstName() + " " +
            emp1100.getLastName() + " after 10% raise: " + emp1100.getYearlySalary
            ());
67     }
68 }

```

1: Employee and EmployeeTest Classes

### 3. Modify the CellPhone Project

3. Modify the CellPhone Project (TextBook page 352) as follows:

- Add a field for discount rate (a double value). For example a discount 10% on the price means 0.1.
- Add method setDiscountRate that takes a non negative value and set it to the discount rate field of the CellPhone class. This method returns true if it runs successfully and false if the argument is invalid.
- Modify the method getRetailPrice so that if the value of discount rate is different to 0, apply the discount on the retail price.
- Write the constructor that initialize all fields using parameters.
- In the CellPhoneTest class, add a new object phone 2 with a discount rate inputted from keyboard and display all information about this phone.

Figure 2: Problem 3 Task Requirement

```
1  /**
2   * The CellPhone class holds data about a cell phone.
3   */
4
5  public class CellPhone {
6
7      // Fields
8      private String manufact; // Manufacturer
9      private String model;    // Model
10     private double retailPrice; // Retail price
11
12     private double discountRate;
13
14     /**
15      * Constructor
16      * @param man The phone's manufacturer.
17      * @param mod The phone's model number.
18      * @param price The phone's retail price.
19      */
20     public CellPhone(String man, String mod, double price) {
21         manufact = man;
22         model = mod;
23         retailPrice = price;
24     }
25
26     public CellPhone(String man, String mod, double price, double discount) {
27         manufact = man;
28         model = mod;
29         retailPrice = price;
30         discountRate = discount;
31     }
32

139         System.out.println();
140         System.out.print("Enter the discount for phone 2: ");
141         discount = keyboard.nextDouble();
142         phone2.setDiscountRate(discount);

144         System.out.println();
145         System.out.println("Here is the data that you provided:");
146         System.out.println("Manufacturer: " + phone2.getManufact());
147         System.out.println("Model number: " + phone2.getModel());
148         System.out.println("Discount rate: " + phone2.getDiscountRate());
149         System.out.println("Retail price: " + phone2.getRetailPrice());

151         keyboard.close();
152     }
153 }

```

## 2: CellPhone and CellPhoneTest Classes

## 6.5

### 5. Payroll Class

Design a Payroll class that has fields for an employee's name, ID number, hourly pay rate, and number of hours worked. Write the appropriate accessor and mutator methods and a constructor that accepts the employee's name and ID number as arguments. The class should also have a method that returns the employee's gross pay, which is calculated as the number of hours worked multiplied by the hourly pay rate. Write a program that demon-

### 6 A First Look at Classes

strates the class by creating a Payroll object, then asking the user to enter the data for an employee. The program should display the amount of gross pay earned.

Figure 3: 6.5 Task Requirement

```
1 public class payroll {
2     private String employeeName;
3     private String id;
4     private double hourlyRate = 0.0;
5     private int hourWorked = 0;
6
7     payroll(String employeeName, String id) {
8         this.employeeName = employeeName;
9         this.id = id;
10    }
11
12    public String getName() {
13        return employeeName;
14    }
15
16    public String getId() {
17        return id;
18    }
19
20    public double getHourlyRate() {
21        return hourlyRate;
22    }
23
24    public int getHourWorked() {
25        return hourWorked;
26    }
27
28    public double getGrossPay() {
29        return hourlyRate * hourWorked;
30    }
31
32    public void setEmployeeName(String employeeName) {
```

```

33     this.employeeName = employeeName;
34 }

36 public void setId(String id) {
37     this.id = id;
38 }

40 public void setHourlyRate(double hourlyRate) {
41     if (hourlyRate > 0) {
42         this.hourlyRate = hourlyRate;
43     }
44 }

46 public void setHourWorked(int hourWorked) {
47     if (hourWorked > 0) {
48         this.hourWorked = hourWorked;
49     }
50 }
51 }

53 import java.util.Scanner;

55 public class payRollTest {
56     public static void main(String[] args) {

58         payRoll PRex = new payRoll("test", "0000");

60         Scanner sc = new Scanner(System.in);

62         System.out.println();
63         System.out.println("Please enter the information for a new employee: ");
64         System.out.print("Name: ");
65         PRex.setEmployeeName(sc.nextLine());

67         System.out.print("Employee id: ");
68         PRex.setId(sc.nextLine());

70         System.out.print("Employee's hourly rate: ");
71         PRex.setHourlyRate(sc.nextDouble());

73         System.out.print("How many hours have they worked? ");
74         PRex.setHourWorked(sc.nextInt());

76         System.out.println("Employee " + PRex.getName() + " gross pay: " + PRex.
            getGrossPay());

78         sc.close();
79     }
80 }

```

### 3: payRoll and payRollTest Classes

## 6.6

### 6. TestScores Class

Design a TestScores class that has fields to hold three test scores. The class should have a constructor, accessor and mutator methods for the test score fields, and a method that returns the average of the test scores. Demonstrate the class by writing a separate program that creates an instance of the class. The program should ask the user to enter three test scores, which are stored in the TestScores object. Then the program should display the average of the scores, as reported by the TestScores object.

Figure 4: 6.6 Task Requirement

```
1 import java.util.Scanner;

3 public class Main {
4     public static void main(String[] args) {
5         double CS310Score;
6         double CS365Score;
7         double CS360Score;
8         Scanner sc = new Scanner(System.in);

10        TestScore TrungTS = new TestScore(10, 10, 10);
11        System.out.println(TrungTS.getAverageScore());

13        System.out.print("Enter the first subject score: ");
14        CS310Score = sc.nextDouble();

16        System.out.print("Enter the second subject score: ");
17        CS365Score = sc.nextDouble();

19        System.out.print("Enter the third subject score: ");
20        CS360Score = sc.nextDouble();

22        TestScore Fall2024TrungTS = new TestScore(CS310Score, CS365Score,
23            CS360Score);
24        System.out.println("Your Fall 2024 average tests score: " +
25            Fall2024TrungTS.getAverageScore());

26        sc.close();
27    }
28 }

29 public class TestScore {
30     private double testScore1;
31     private double testScore2;
32     private double testScore3;

34     TestScore(double testScore1, double testScore2, double testScore3) {
35         if ((testScore1 >= 0 && testScore2 >= 0 && testScore3 >= 0) &&
36             (testScore1 <= 10 && testScore2 <= 10 && testScore3 <= 10)) {
37             this.testScore1 = testScore1;
38             this.testScore2 = testScore2;
39             this.testScore3 = testScore3;
40         }
41     }
}
```

```

43     public double getTestScore1() {
44         return testScore1;
45     }

47     public double getTestScore2() {
48         return testScore2;
49     }

51     public double getTestScore3() {
52         return testScore3;
53     }

55     public void setTestScore1(double testScore1) {
56         if (testScore1 >= 0 && testScore1 <= 10) {
57             this.testScore1 = testScore1;
58         }
59     }

61     public void setTestScore2(double testScore2) {
62         if (testScore2 >= 0 && testScore2 <= 10) {
63             this.testScore2 = testScore2;
64         }
65     }

67     public void setTestScore3(double testScore3) {
68         if (testScore3 >= 0 && testScore3 <= 10) {
69             this.testScore3 = testScore3;
70         }
71     }

73     public double getAverageScore() {
74         return (this.testScore1 + this.testScore2 + this.testScore3) / 3;
75     }
76 }

```

#### 4: Main and TestScore Classes

**8. Temperature Class**

Write a `Temperature` class that will hold a temperature in Fahrenheit, and provide methods to get the temperature in Fahrenheit, Celsius, and Kelvin. The class should have the following field:

- `ftemp` – A double that holds a Fahrenheit temperature.

The class should have the following methods:

- Constructor – The constructor accepts a Fahrenheit temperature (as a double) and stores it in the `ftemp` field.
- `setFahrenheit` – The `setFahrenheit` method accepts a Fahrenheit temperature (as a double) and stores it in the `ftemp` field.
- `getFahrenheit` – Returns the value of the `ftemp` field, as a Fahrenheit temperature (no conversion required).
- `getCelsius` – Returns the value of the `ftemp` field converted to Celsius.
- `getKelvin` – Returns the value of the `ftemp` field converted to Kelvin.

## Programming Challenges

Use the following formula to convert the Fahrenheit temperature to Celsius:

$$\text{Celsius} = (5/9) \times (\text{Fahrenheit} - 32)$$

Use the following formula to convert the Fahrenheit temperature to Kelvin:

$$\text{Kelvin} = ((5/9) \times (\text{Fahrenheit} - 32)) + 273$$

Demonstrate the `Temperature` class by writing a separate program that asks the user for a Fahrenheit temperature. The program should create an instance of the `Temperature` class, with the value entered by the user passed to the constructor. The program should then call the object's methods to display the temperature in Celsius and Kelvin.

Figure 5: 6.8 Task Requirement

```

1 import java.util.Scanner;
2
3 public class Temperature {
4     private double ftemp;
5
6     Temperature(double ftemp) {
7         this.ftemp = ftemp;
8     }
9
10    public double getFahrenheit() {
11        return ftemp;
12    }
13
14    public double getCelsius() {

```

```

15         return (5.0 / 9) * (ftemp - 32);
16     }

18     public double getKelvin() {
19         return ((5.0 / 9) * (ftemp - 32)) + 273;
20     }

22     public void setFahrenheit(double Fahrenheit) {
23         this.ftemp = Fahrenheit;
24     }

26     public static void main(String[] args) {
27         Scanner sc = new Scanner(System.in);

29         System.out.print("Enter a temperature in Fahrenheit: ");
30         double ftemp = sc.nextDouble();

32         Temperature temp = new Temperature(ftemp);

34         System.out.println("Temperature in Fahrenheit: " + temp.getFahrenheit());
35         System.out.printf("Temperature in Celsius: %.2f\n", temp.getCelsius());
36         System.out.printf("Temperature in Kelvin: %.2f\n", temp.getKelvin());

38         sc.close();
39     }
40 }

```

5: Temperature Class

## Assignment 8

Contributor: Nguyen Quang Huy - 1677664

### 7.1

#### 1. Rainfall Class

Write a RainFall class that stores the total rainfall for each of 12 months into an array of doubles. The program should have methods that return the following:

- the total rainfall for the year
- the average monthly rainfall
- the month with the most rain
- the month with the least rain

Demonstrate the class in a complete program.

*Input Validation: Do not accept negative numbers for monthly rainfall figures.*

Figure 6: 7.1 Task Requirement

```

1 // Rainfall.java
2 public class Rainfall {
3     private double[] monthlyRainfall;

5     // Constructor with input validation

```

```

6    public Rainfall(double[] rainfall) {
7        monthlyRainfall = new double[12];
8        for (int i = 0; i < 12; i++) {
9            if (rainfall[i] < 0) {
10               throw new IllegalArgumentException("Rainfall figures cannot be
11                  negative.");
12            }
13            monthlyRainfall[i] = rainfall[i];
14        }
15    }
16
17    // Calculate total rainfall
18    public double getTotalRainfall() {
19        double total = 0;
20        for (double rain : monthlyRainfall) {
21            total += rain;
22        }
23        return total;
24    }
25
26    // Calculate average monthly rainfall
27    public double getAverageRainfall() {
28        return getTotalRainfall() / monthlyRainfall.length;
29    }
30
31    // Find the month with the most rain
32    public int getMonthWithMostRain() {
33        int month = 0;
34        double maxRain = monthlyRainfall[0];
35        for (int i = 1; i < monthlyRainfall.length; i++) {
36            if (monthlyRainfall[i] > maxRain) {
37                maxRain = monthlyRainfall[i];
38                month = i;
39            }
40        }
41        return month + 1; // Return month (1-12)
42    }
43
44    // Find the month with the least rain
45    public int getMonthWithLeastRain() {
46        int month = 0;
47        double minRain = monthlyRainfall[0];
48        for (int i = 1; i < monthlyRainfall.length; i++) {
49            if (monthlyRainfall[i] < minRain) {
50                minRain = monthlyRainfall[i];
51                month = i;
52            }
53        }
54        return month + 1; // Return month (1-12)
55    }

```

6: Rainfall.java

```

1 // RainfallDemo.java
2 import java.util.Scanner;
3
4 public class RainfallDemo {
5     public static void main(String[] args) {

```

```

6      Scanner input = new Scanner(System.in);
7      double[] rainfall = new double[12];

9      System.out.println("Enter the total rainfall for each month:");

11     // Input rainfall data with validation
12     for (int i = 0; i < 12; i++) {
13         while (true) {
14             System.out.print("Month " + (i + 1) + ": ");
15             rainfall[i] = input.nextDouble();
16             if (rainfall[i] < 0) {
17                 System.out.println("Rainfall cannot be negative. Please enter
18                                     a valid number.");
19             } else {
20                 break;
21             }
22         }

24     // Create Rainfall object and call methods
25     Rainfall rainData = new Rainfall(rainfall);

27     // Display results
28     System.out.printf("Total Rainfall: %.2f\n", rainData.getTotalRainfall());
29     System.out.printf("Average Monthly Rainfall: %.2f\n", rainData.
30                         getAverageRainfall());
31     System.out.println("Month with Most Rain: " + rainData.
32                         getMonthWithMostRain());
33     System.out.println("Month with Least Rain: " + rainData.
34                         getMonthWithLeastRain());

35     input.close();
}

```

7: RainFallDemo.java

## 7.2

### 2. Payroll Class

Write a Payroll class that uses the following arrays as fields:

- **employeeId**. An array of seven integers to hold employee identification numbers. The array should be initialized with the following numbers:  
5658845 4520125 7895122 8777541  
8451277 1302850 7580489
- **hours**. An array of seven integers to hold the number of hours worked by each employee
- **payRate**. An array of seven doubles to hold each employee's hourly pay rate
- **wages**. An array of seven doubles to hold each employee's gross wages

The class should relate the data in each array through the subscripts. For example, the number in element 0 of the hours array should be the number of hours worked by the employee whose identification number is stored in element 0 of the employeeId array. That same employee's pay rate should be stored in element 0 of the payRate array.

In addition to the appropriate accessor and mutator methods, the class should have a method that accepts an employee's identification number as an argument and returns the gross pay for that employee.

### Programming Challenges

Demonstrate the class in a complete program that displays each employee number and asks the user to enter that employee's hours and pay rate. It should then display each employee's identification number and gross wages.

*Input Validation: Do not accept negative values for hours or numbers less than 6.00 for pay rate.*

Figure 7: 7.2 Task Requirement

```
1 // Payroll.java
2 public class Payroll {
3     // Declare arrays for fields
4     private int[] employeeId = { 5658845, 4520125, 7895122, 8777541, 8451277,
5                                   1302850, 7580489 };
6     private int[] hours = new int[7];           // Hours worked by each employee
7     private double[] payRate = new double[7];   // Hourly pay rate
8     private double[] wages = new double[7];     // Total wages for each employee
9
10    // Set hours worked with input validation
11    public void setHours(int index, int hoursWorked) {
12        if (hoursWorked < 0) {
13            throw new IllegalArgumentException("Hours cannot be negative.");
14        }
15    }
16 }
```

```

14         hours[index] = hoursWorked;
15     }

17     // Set pay rate with input validation
18     public void setPayRate(int index, double rate) {
19         if (rate < 6.00) {
20             throw new IllegalArgumentException("Pay rate must be at least 6.00.");
21         }
22         payRate[index] = rate;
23     }

25     // Calculate wages for each employee
26     public void calculateWages() {
27         for (int i = 0; i < employeeId.length; i++) {
28             wages[i] = hours[i] * payRate[i];
29         }
30     }

32     // Return employee ID
33     public int getEmployeeId(int index) {
34         return employeeId[index];
35     }

37     // Return total wages for an employee
38     public double getWages(int index) {
39         return wages[index];
40     }
41 }

```

8: Payroll.java

```

1 // PayrollDemo.java
2 import java.util.Scanner;

4 public class PayrollDemo {
5     public static void main(String[] args) {
6         Scanner input = new Scanner(System.in);
7         Payroll payroll = new Payroll();

9         System.out.println("Enter hours worked and pay rate for each employee:");

11        // Loop to input data for each employee
12        for (int i = 0; i < 7; i++) {
13            int hoursWorked;
14            double payRate;

16            // Display employee ID
17            System.out.println("Employee ID: " + payroll.getEmployeeId(i));

19            // Input hours worked with validation
20            while (true) {
21                System.out.print("Enter hours worked: ");
22                hoursWorked = input.nextInt();
23                if (hoursWorked >= 0) {
24                    break;
25                }
26                System.out.println("Hours cannot be negative. Please try again.");
27            }
28            payroll.setHours(i, hoursWorked);

```

```

30         // Input hourly pay rate with validation
31         while (true) {
32             System.out.print("Enter hourly pay rate: ");
33             payRate = input.nextDouble();
34             if (payRate >= 6.00) {
35                 break;
36             }
37             System.out.println("Pay rate must be at least 6.00. Please try
again.");
38         }
39         payroll.setPayRate(i, payRate);
40     }

42     // Calculate wages
43     payroll.calculateWages();

45     // Display results
46     System.out.println("\nEmployee Wages:");
47     for (int i = 0; i < 7; i++) {
48         System.out.printf("Employee ID: %d | Gross Wages: %.2f\n",
49                             payroll.getEmployeeId(i), payroll.getWages(i));
50     }

52     input.close();
53 }
54 }

```

9: PayrollDemo.java

## 7.3

### 3. Charge Account Validation

Create a class with a method that accepts a charge account number as its argument. The method should determine whether the number is valid by comparing it to the following list of valid charge account numbers:

5658845	4520125	7895122	8777541	8451277	1302850
8080152	4562555	5552012	5050552	7825877	1250255
1005231	6545231	3852085	7576651	7881200	4581002

These numbers should be stored in an array or an `ArrayList` object. Use a sequential search to locate the number passed as an argument. If the number is in the array, the method should return `true`, indicating the number is valid. If the number is not in the array, the method should return `false`, indicating the number is invalid.

Write a program that tests the class by asking the user to enter a charge account number. The program should display a message indicating whether the number is valid or invalid.

Figure 8: 7.3 Task Requirement

```

1 public class ChargeAccount {
2     private int[] validAccountNumbers = {
3         5658845, 4520125, 7895122, 8777541, 8451277, 1302850,
4         8080152, 4562555, 5552012, 5050552, 7825877, 1250255,
5         1005231, 6545231, 3852085, 7576651, 7881200, 4581002
6     };

```

```

9     public boolean isValidAccount(int accountNumber) {
10         for (int validNumber : validAccountNumbers) {
11             if (validNumber == accountNumber) {
12                 return true;
13             }
14         }
15         return false;
16     }
17 }

```

10: ChargeAccount.java

```

1 import java.util.Scanner;

3 public class ChargeAccountDemo {
4     public static void main(String[] args) {
5         Scanner input = new Scanner(System.in);
6         ChargeAccount accountValidator = new ChargeAccount();

9         System.out.print("Enter a charge account number to validate: ");
10        int accountNumber = input.nextInt();

12        if (accountValidator.isValidAccount(accountNumber)) {
13            System.out.println("The account number " + accountNumber + " is VALID.
14                                ");
15        } else {
16            System.out.println("The account number " + accountNumber + " is
17                                INVALID.");
18        }

19        input.close();
20    }
}

```

11: ChargeAccountDemo.java

## 2. Circle class

2. Write a Circle class that has: its radius as a real number, its color as a string such as "red" "blue".

The accessors and mutators for these attributes and one new member function `getArea` to calculate the circle's area.

Write a program demonstrating the Circle class by asking the user for the circle's radius, color and creating a Circle object, and then reporting the circle's area and color.

Figure 9: Problem 2 Task Requirement

```

1 public class Circle {

3     private double radius;
4     private String color;

```

```

6     public Circle(double radius, String color) {
7         this.radius = radius;
8         this.color = color;
9     }

11    public double getRadius() {
12        return radius;
13    }

15    public String getColor() {
16        return color;
17    }

19    public void setRadius(double radius) {
20        this.radius = radius;
21    }

23    public void setColor(String color) {
24        this.color = color;
25    }

27    public double getArea() {
28        return Math.PI * Math.pow(radius, 2);
29    }
30 }

```

12: Circle.java

```

1  import java.util.Scanner;

3  public class CircleTest {
4      public static void main(String[] args) {

6          Scanner scanner = new Scanner(System.in);

8          System.out.print("Enter radius: ");
9          double radius = scanner.nextDouble();
10         scanner.nextLine();

12         String color = "";
13         boolean validColor = false;
14         while (!validColor) {
15             System.out.print("Enter color (red or blue): ");
16             color = scanner.nextLine().toLowerCase();
17             if (color.equals("red") || color.equals("blue")) {
18                 validColor = true;
19             } else {
20                 System.out.println("Invalid color. Please enter 'red' or 'blue'.")
21                 ;
22             }
23         }

24         Circle circle = new Circle(radius, color);

26         System.out.printf("The area is: %.2f\n", circle.getArea());
27         System.out.println("The color is: " + circle.getColor());

29         scanner.close();
30     }

```

### 3. Employee class

3. Create a class called Employee that includes three pieces of information as data members—a first name (type string), a last name (type string) and a monthly salary (type int).

Provide a set and a get function for each data member. If the monthly salary is not positive, set it to 0. Write a test program that demonstrates class Employee's capabilities.

Create two Employee objects and display each object's yearly salary. Then give each Employee a 10 percent raise and display each Employee's yearly salary again.

Figure 10: Problem 3 Requirement

```
1 public class Employee {  
3     private String firstName;  
4     private String lastName;  
5     private int monthlySalary;  
  
7     public Employee(String firstName, String lastName, int monthlySalary) {  
8         this.firstName = firstName;  
9         this.lastName = lastName;  
10        this.monthlySalary = monthlySalary;  
11    }  
  
13    public String getFirstName() {  
14        return firstName;  
15    }  
  
17    public void setFirstName(String firstName) {  
18        this.firstName = firstName;  
19    }  
  
21    public String getLastName() {  
22        return lastName;  
23    }  
  
25    public void setLastName(String lastName) {  
26        this.lastName = lastName;  
27    }  
  
29    public int getMonthlySalary() {  
30        return monthlySalary;  
31    }  
  
33    public void setMonthlySalary(int monthlySalary) {  
34        if (monthlySalary > 0) {  
35            this.monthlySalary = monthlySalary;  
36        } else {  
37            this.monthlySalary = 0;  
38        }  
    }  
}
```

```

39     }

41     public int getYearlySalary() {
42         return monthlySalary * 12;
43     }

45     public void applyRaise() {
46         monthlySalary += monthlySalary * 0.10;
47     }
48 }

```

14: Employee.java

```

1 public class EmployeeTest {
2     public static void main(String[] args) {
3         Employee employee1 = new Employee("Quang", "Huy", 3000);
4         Employee employee2 = new Employee("Naruto", "Sasuke", 2500);

6         System.out.println(employee1.getFirstName() + " " + employee1.getLastName
7             () +
8             "'s yearly salary: " + employee1.getYearlySalary());
9         System.out.println(employee2.getFirstName() + " " + employee2.getLastName
10            () +
11            "'s yearly salary: " + employee2.getYearlySalary());

12         employee1.applyRaise();
13         employee2.applyRaise();

14         System.out.println("After 10% raise:");
15         System.out.println(employee1.getFirstName() + " " + employee1.getLastName
16             () +
17             "'s yearly salary: " + employee1.getYearlySalary());
18         System.out.println(employee2.getFirstName() + " " + employee2.getLastName
19             () +
20             "'s yearly salary: " + employee2.getYearlySalary());
21     }
22 }

```

15: EmployeeTest.java

## 4. Account class

4. Create an Account class that a bank might use to represent customers' bank accounts. Include a data member of type double to represent the account balance and an account number of type string. Provide 4 member functions. Member function credit should add an amount to the current balance. Member function debit should withdraw money from the Account and ensure that the debit amount does not exceed the Account's balance. If it does the balance should be left unchanged and the function should print a message indicating "Debit amount exceeded account balance." Member function getBalance should return the current balance.

- A pair of get/setAccountNumber should be implemented.
- Write a program that creates two Account objects and tests the member functions of class Account as follows:
  - Account number 122100008121 – credit balance 1.000.050 – then debit 2000.000
  - Account number 122100008121 – credit balance 2.000.050 – then debit 2000.000
- Display information about each account after each transaction.

Figure 11: Problem 4 Requirement

```
1 public class Account {
2     private double balance;
3     private String accountNumber;
4
5     public Account(String accNumber, double initialBalance) {
6         accountNumber = accNumber;
7         balance = initialBalance;
8     }
9
10    public void credit(double amount) {
11        balance += amount;
12    }
13
14    public void debit(double amount) {
15        if (amount > balance) {
16            System.out.println("Debit amount exceeded account balance.");
17        } else {
18            balance -= amount;
19        }
20    }
21
22    public double getBalance() {
23        return balance;
24    }
25
26    public String getAccountNumber() {
27        return accountNumber;
28    }
29
30    public void setAccountNumber(String accNumber) {
31        accountNumber = accNumber;
32    }
33 }
```

```

34     public void displayAccountInfo() {
35         System.out.println("Account number: " + accountNumber);
36         System.out.println("Balance: " + balance);
37     }
38 }

```

16: Account.java

```

1 public class ATM {
2     public static void main(String[] args) {
3         Account account1 = new Account("122100008121", 1000050);
4         Account account2 = new Account("122100008121", 2000050);
5
6         System.out.println("Before transactions:");
7         account1.displayAccountInfo();
8         account2.displayAccountInfo();
9
10        account1.credit(1000050);
11        account1.debit(2000000);
12
13        account2.credit(2000050);
14        account2.debit(2000000);
15
16        System.out.println("After transaction:");
17        account1.displayAccountInfo();
18        account2.displayAccountInfo();
19    }
20 }

```

## 1. Complex class

### 1. Develop the Complex class as the following specification in C++ and Java:

```
#ifndef COMPLEX_H
#define COMPLEX_H

class Complex {
private:
    double real;
    double imag;
public:
    Complex(double real = 0.0, double imag = 0.0);
    double getReal() const;
    void setReal(double real);
    double getImag() const;
    void setImag(double imag);
    void setValue(double real, double imag);
    void print() const;
    bool isReal() const;
    bool isImaginary() const;
    // Add the given Complex instance into this instance, and return this instance by reference
    Complex & addInto(const Complex & another);
    Complex & addInto(double real, double imag);
    // Add the given Complex instance and this instance, return the sum in a new instance by value
    Complex addReturnNew(const Complex & another) const;
    Complex addReturnNew(double real, double imag) const;
};

#endif
```

Figure 12: Problem 1

### 1. C++

```
1 #include "Complex.h"
2 #include <iostream>
3
4 using namespace std;
5
6 Complex::Complex(double real, double imag) : real(real), imag(imag) {}
7
8 double Complex::getReal() const {
9     return real;
10 }
11
12 void Complex::setReal(double real) {
13     this->real = real;
14 }
15
16 double Complex::getImag() const {
17     return imag;
18 }
19
20 void Complex::setImag(double imag) {
21     this->imag = imag;
22 }
23
24 void Complex::setValue(double real, double imag) {
```

```

25     this->real = real;
26     this->imag = imag;
27 }

29 void Complex::print() const {
30     cout << real;
31     if (imag >= 0) {
32         cout << " + " << imag << "i" << endl;
33     } else {
34         cout << " - " << -imag << "i" << endl;
35     }
36 }

38 bool Complex::isReal() const {
39     return imag == 0.0;
40 }

42 bool Complex::isImaginary() const {
43     return real == 0.0;
44 }

46 Complex & Complex::addInto(const Complex & another) {
47     this->real += another.real;
48     this->imag += another.imag;
49     return *this;
50 }

52 Complex & Complex::addInto(double real, double imag) {
53     this->real += real;
54     this->imag += imag;
55     return *this;
56 }

58 Complex Complex::addReturnNew(const Complex & another) const {
59     return Complex(this->real + another.real, this->imag + another.imag);
60 }

62 Complex Complex::addReturnNew(double real, double imag) const {
63     return Complex(this->real + real, this->imag + imag);
64 }

```

18: Complex.cpp

```

1  #ifndef COMPLEX_H
2  #define COMPLEX_H

4  class Complex {
5  private:
6      double real;
7      double imag;

9  public:
10     Complex(double real = 0.0, double imag = 0.0);

12     double getReal() const;
13     void setReal(double real);

15     double getImag() const;
16     void setImag(double imag);

```

```

18     void setValue(double real, double imag);

20     void print() const;

22     bool isReal() const;
23     bool isImaginary() const;

25     Complex & addInto(const Complex & another);
26     Complex & addInto(double real, double imag);

28     Complex addReturnNew(const Complex & another) const;
29     Complex addReturnNew(double real, double imag) const;
30 };

32 #endif

```

19: Complex.h

```

1 #include <iostream>
2 #include "Complex.h"

4 int main() {
5     Complex c1(2.0, 3.0);
6     Complex c2(1.0, 4.0);
7     Complex c3 = c1.addReturnNew(c2);
8     c1.print();
9     c2.print();
10    c3.print();

12    c1.addInto(c2);
13    c1.print();

15    return 0;
16 }

```

20: Main.cpp

## 1. Java

```

1 public class Complex {
2     private double real;
3     private double imag;

5     public Complex(double real, double imag) {
6         this.real = real;
7         this.imag = imag;
8     }

10    public Complex() {
11        this(0.0, 0.0);
12    }

14    public double getReal() {
15        return real;
16    }

18    public void setReal(double real) {

```

```

19         this.real = real;
20     }

22     public double getImag() {
23         return imag;
24     }

26     public void setImag(double imag) {
27         this.imag = imag;
28     }

30     public void setValue(double real, double imag) {
31         this.real = real;
32         this.imag = imag;
33     }

35     public void print() {
36         System.out.print(real);
37         if (imag >= 0) {
38             System.out.println(" + " + imag + "i");
39         } else {
40             System.out.println(" - " + -imag + "i");
41         }
42     }

44     public boolean isReal() {
45         return imag == 0.0;
46     }

48     public boolean isImaginary() {
49         return real == 0.0;
50     }

52     public Complex addInto(Complex another) {
53         this.real += another.real;
54         this.imag += another.imag;
55         return this;
56     }

58     public Complex addInto(double real, double imag) {
59         this.real += real;
60         this.imag += imag;
61         return this;
62     }

64     public Complex addReturnNew(Complex another) {
65         return new Complex(this.real + another.real, this.imag + another.imag);
66     }

68     public Complex addReturnNew(double real, double imag) {
69         return new Complex(this.real + real, this.imag + imag);
70     }
71 }

```

21: Complex.java

```

1 public class TestComplex {
2     public static void main(String[] args) {

```

```

4      Complex c1 = new Complex(2.0, 3.0);
5      Complex c2 = new Complex(1.0, 4.0);
6      Complex c3 = c1.addReturnNew(c2);
7      c1.print();
8      c2.print();
9      c3.print();

11     c1.addInto(c2);
12     c1.print();
13 }
14 }

```

22: TestComplex.java

## 2. Date class

2. Implement the class Date in C++ (**Date.h, Date.cpp**)/Java

Date
-year:int -month:int -day:int -STR MONTHS:string[] = {"Jan","Feb","Mar","Apr","May","Jun", "Jul","Aug","Sep","Oct","Nov","Dec"} -STR DAY:string[] = {"Sunday","Monday","Tuesday","Wednesday", "Thursday","Friday","Saturday"} -DAYS_IN_MONTH:int[] = {31,28,31,30,31,30,31,31,30,31,30,31}
+isLeapYear(year:int):bool +isValidDate(year:int, month:int, day:int):bool +getDayOfWeek(year:int, month:int, day:int):int +Date(year:int, month:int, day:int) +setDate(year:int, month:int, day:int):void +getYear():int +getMonth():int +getDay():int +setYear(year:int):void +setMonth(month:int):void +setDay(day:int):void +print():void +nextDay():Date& +previousDay():Date& +nextMonth():Date& +previousMonth():Date& +nextYear():Date& +previousYear():Date&

Then test the class (TestDate.cpp) in a program that create the dates Sunday, 1 Jan 2012, Tuesday, 31 Jan 2012, Monday, 31 Dec 2012 then display information about the next day. Display the previous day of 1/1/2012 and the day after one year of 29/02/2012

Figure 13: Problem 2

## 2. C++

```

1 #include "Date.h"
2 #include <iostream>
3 #include <string>

```

```

5 Date::Date(int day, int month, int year) : day(day), month(month), year(year) {}

7 int Date::getDay() const {

## 13.13

### 13. Mortgage Payment

Design a class that will determine the monthly payment on a home mortgage. The monthly payment with interest compounded monthly can be calculated as follows:

$$\text{Payment} = \frac{\text{Loan} \times \frac{\text{Rate}}{12} \times \text{Term}}{\text{Term} - 1}$$

where

$$\text{Term} = \left(1 + \frac{\text{Rate}}{12}\right)^{12 \times \text{Years}}$$

Payment = the monthly payment

Loan = the dollar amount of the loan

Rate = the annual interest rate

Years = the number of years of the loan

The class should have member functions for setting the loan amount, interest rate, and number of years of the loan. It should also have member functions for returning

Review Questions and Exercises

the monthly payment amount and the total amount paid to the bank at the end of the loan period. Implement the class in a complete program.

*Input Validation: Do not accept negative numbers for any of the loan values.*

## Assignment 11

Contributor: Nguyen Duy Duc - 1624838

# Java

## 8.1

### 1. Area Class

Write a class that has three overloaded static methods for calculating the areas of the following geometric shapes:

- circles
- rectangles
- cylinders

### 8 A Second Look at Classes and Objects

Here are the formulas for calculating the area of the shapes.

Area of a circle:  $Area = \pi r^2$   
where  $\pi$  is `Math.PI` and  $r$  is the circle's radius

Area of a rectangle:  $Area = Width \times Length$

Area of a cylinder:  $Area = \pi r^2 h$   
where  $\pi$  is `Math.PI`,  $r$  is the radius of the cylinder's base, and  $h$  is the cylinder's height

Because the three methods are to be overloaded, they should each have the same name, but different parameter lists. Demonstrate the class in a complete program.

Figure 15: 8.1 Task Requirement

```
1 public class Area {  
2  
3     // Area of a circle  
4     public static double calculateArea(double radius) {  
5         return Math.PI * radius * radius;  
6     }  
7  
8     // Area of a rectangle  
9     public static double calculateArea(double width, double length) {  
10        return width * length;  
11    }  
12  
13    // Area of a cylinder  
14    public static double calculateArea(double radius, double height, boolean  
15        isCylinder) {  
16        return Math.PI * radius * radius * height;  
17    }  
}
```

34: Area.java

```

1 import java.util.Scanner;

3 public class AreaDemo {
4     public static void main(String[] args) {
5         Scanner scanner = new Scanner(System.in);

7         System.out.println("Select a shape to calculate the area:");
8         System.out.println("1. Circle");
9         System.out.println("2. Rectangle");
10        System.out.println("3. Cylinder");

12        int choice = scanner.nextInt();

14        switch (choice) {
15            case 1:
16                // Circle
17                System.out.print("Enter the radius of the circle: ");
18                double radiusCircle = scanner.nextDouble();
19                double circleArea = Area.calculateArea(radiusCircle);
20                System.out.printf("The area of the circle is: %.2f\n", circleArea);
21                ;
22                break;

23            case 2:
24                // Rectangle
25                System.out.print("Enter the width of the rectangle: ");
26                double width = scanner.nextDouble();
27                System.out.print("Enter the length of the rectangle: ");
28                double length = scanner.nextDouble();
29                double rectangleArea = Area.calculateArea(width, length);
30                System.out.printf("The area of the rectangle is: %.2f\n",
31                    rectangleArea);
32                break;

33            case 3:
34                // Cylinder
35                System.out.print("Enter the radius of the cylinder: ");
36                double radiusCylinder = scanner.nextDouble();
37                System.out.print("Enter the height of the cylinder: ");
38                double height = scanner.nextDouble();
39                double cylinderArea = Area.calculateArea(radiusCylinder, height,
40                    true);
41                System.out.printf("The area of the cylinder is: %.2f\n",
42                    cylinderArea);
43                break;

44            default:
45                System.out.println("Invalid choice! Please select 1, 2, or 3.");
46        }

47        scanner.close();
48    }
49 }

```

35: AreaDemo.java

## 8.2

### 2. BankAccount Class Copy Constructor

Add a copy constructor to the BankAccount class. This constructor should accept a BankAccount object as an argument. It should assign to the balance field the value in the argument's balance field. As a result, the new object will be a copy of the argument object.

Figure 16: 8.2 Task Requirement

```
1 public class BankAccount {
2     private double balance;

3
4     // Constructor
5     public BankAccount(double initialBalance) {
6         balance = initialBalance;
7     }

8
9     // Copy constructor
10    public BankAccount(BankAccount account) {
11        this.balance = account.balance;
12    }

13
14    public double getBalance() {
15        return balance;
16    }

17
18    public void deposit(double amount) {
19        balance += amount;
20    }

21
22    public void withdraw(double amount) {
23        if (amount <= balance) {
24            balance -= amount;
25        } else {
26            System.out.println("Insufficient funds.");
27        }
28    }

29
30    public static void main(String[] args) {
31        // Create a BankAccount object
32        BankAccount account1 = new BankAccount(1000.0);

33
34        // Create a copy of account1
35        BankAccount account2 = new BankAccount(account1);

36
37        // Display the balances
38        System.out.println("Balance of account1: " + account1.getBalance());
39        System.out.println("Balance of account2: " + account2.getBalance());
40    }
41 }
```

36: BankAccount.java

### 3. Carpet Calculator

The Westfield Carpet Company has asked you to write an application that calculates the price of carpeting for rectangular rooms. To calculate the price, you multiply the area of the floor (width times length) by the price per square foot of carpet. For example, the area of floor that is 12 feet long and 10 feet wide is 120 square feet. To cover that floor with carpet that costs \$8 per square foot would cost \$960. ( $12 \times 10 \times 8 = 960$ .)

First, you should create a class named `RoomDimension` that has two fields: one for the length of the room and one for the width. The `RoomDimension` class should have a method that returns the area of the room. (The area of the room is the room's length multiplied by the room's width.)

Next you should create a `RoomCarpet` class that has a `RoomDimension` object as a field. It should also have a field for the cost of the carpet per square foot. The `RoomCarpet` class should have a method that returns the total cost of the carpet.

Figure 8-21 is a UML diagram that shows possible class designs and the relationships among the classes. Once you have written these classes, use them in an application that asks the user to enter the dimensions of a room and the price per square foot of the desired carpeting. The application should display the total cost of the carpet.

Figure 17: 8.3 Task Requirement

```

1 import java.util.Scanner;

3 public class CarpetCalculator {
4     public static void main(String[] args) {
5         Scanner scanner = new Scanner(System.in);

7         // Get the dimensions
8         System.out.print("Enter the length of the room in feet: ");
9         double length = scanner.nextDouble();

11        System.out.print("Enter the width of the room in feet: ");
12        double width = scanner.nextDouble();

14        // Create a RoomDimension object
15        RoomDimension roomDimension = new RoomDimension(length, width);

17        // Get the cost per square foot of the carpet
18        System.out.print("Enter the cost per square foot of the carpet: ");
19        double costPerSquareFoot = scanner.nextDouble();

21        // Create a RoomCarpet object
22        RoomCarpet roomCarpet = new RoomCarpet(roomDimension, costPerSquareFoot);

24        // Display the total cost
25        System.out.println("The total cost of the carpet: $" + roomCarpet.
26                           getTotalCost());
27    }
}

```

37: CarpetCalculator.java

```

1 class RoomCarpet {

```

```

2     private RoomDimension dimension;
3     private double costPerSquareFoot;

5     // Constructor
6     public RoomCarpet(RoomDimension dimension, double costPerSquareFoot) {
7         this.dimension = dimension;
8         this.costPerSquareFoot = costPerSquareFoot;
9     }

11    public double getTotalCost() {
12        return dimension.getArea() * costPerSquareFoot;
13    }
14 }

```

38: RoomCarpet.java

```

1 class RoomDimension {
2     private double length;
3     private double width;

5     // Constructor
6     public RoomDimension(double length, double width) {
7         this.length = length;
8         this.width = width;
9     }

11    public double getArea() {
12        return length * width;
13    }
14 }

```

39: RoomDimension.java

# C++

## 14.1

### 1. Numbers Class

Design a class `Numbers` that can be used to translate whole dollar amounts in the range 0 through 9999 into an English description of the number. For example, the number 713 would be translated into the string *seven hundred thirteen*, and 8203 would be translated into *eight thousand two hundred three*. The class should have a single integer member variable:

```
int number;
```

and a static array of strings that specify how to translate key dollar amounts into the desired format. For example, you might use static strings such as

```
char lessThan20[20][25] = {"zero", "one", ..., "eighteen", "nineteen"};
char hundred[] = "hundred";
char thousand[] = "thousand";
```

The class should have a constructor that accepts a nonnegative integer and uses it to initialize the `Numbers` object. It should have a member function `print()` that prints the English description of the `Numbers` object. Demonstrate the class by writing a main program that asks the user to enter a number in the proper range and then prints out its English description.

Figure 18: 14.1 Task Requirement

```
1 #include <iostream>
2 #include <string>
3
4 using namespace std;
5
6 class Numbers {
7 private:
8     int number;
9     static string lessThan20[20];
10    static string tens[10];
11    static string hundred;
12    static string thousand;
13
14 public:
15     // Constructor
16     Numbers(int num) : number(num) {}
17
18     // Function to print the English description of the number
19     void print() const {
20         if (number == 0) {
21             cout << lessThan20[0] << endl;
22             return;
23         }
24
25         string result;
26         int tempNumber = number;
27
28         if (tempNumber >= 1000) {
29             result += lessThan20[tempNumber / 1000] + " " + thousand + " ";
30             tempNumber %= 1000;
```

```

31     }
32     if (tempNumber >= 100) {
33         result += lessThan20[tempNumber / 100] + " " + hundred + " ";
34         tempNumber %= 100;
35     }
36     if (tempNumber >= 20) {
37         result += tens[tempNumber / 10] + " ";
38         tempNumber %= 10;
39     }
40     if (tempNumber > 0) {
41         result += lessThan20[tempNumber] + " ";
42     }
43
44     cout << result << endl;
45 }
46 };
47
48 // Static member initialization
49 string Numbers::lessThan20[20] = {"zero", "one", "two", "three", "four", "five", "
    six", "seven", "eight", "nine", "ten", "eleven", "twelve", "thirteen", "
    fourteen", "fifteen", "sixteen", "seventeen", "eighteen", "nineteen"};
50 string Numbers::tens[10] = {"", "", "twenty", "thirty", "forty", "fifty", "sixty",
    "seventy", "eighty", "ninety"};
51 string Numbers::hundred = "hundred";
52 string Numbers::thousand = "thousand";
53
54 int main() {
55     int num;
56
57     // Loop until a valid number is entered
58     do {
59         cout << "Enter a number between 0 and 9999: ";
60         cin >> num;
61
62         if (num < 0 || num > 9999) {
63             cout << "Number out of range! Please try again." << endl;
64         }
65     } while (num < 0 || num > 9999);
66
67     Numbers number(num);
68     number.print();
69
70     return 0;
71 }

```

40: Numbers.cpp

## 2. Day of the Year

Assuming that a year has 365 days, write a class named `DayOfYear` that takes an integer representing a day of the year and translates it to a string consisting of the month followed by day of the month. For example,

Day 2 would be *January 2*.

Day 32 would be *February 1*.

Day 365 would be *December 31*.

The constructor for the class should take as parameter an integer representing the day of the year, and the class should have a member function `print()` that prints the day in the month-day format. The class should have an integer member variable to represent the day, and should have static member variables holding strings that can be used to assist in the translation from the integer format to the month-day format.

Test your class by inputting various integers representing days and printing out their representation in the month-day format.

Figure 19: 14.2 Task Requirement

```

1 #include <iostream>
2 #include <string>
3
4 using namespace std;
5
6 class DayOfYear {
7 private:
8     int day;
9     static string months[12];
10    static int daysInMonth[12];
11
12 public:
13     // Constructor
14     DayOfYear(int dayOfYear) : day(dayOfYear) {}
15
16     // Function to print the day in month-day format
17     void print() const {
18         int month = 0;
19         int dayOfMonth = day;
20
21         while (dayOfMonth > daysInMonth[month]) {
22             dayOfMonth -= daysInMonth[month];
23             month++;
24         }
25
26         cout << months[month] << " " << dayOfMonth << endl;
27     }
28 };
29
30 // Static member initialization
31 string DayOfYear::months[12] = {"January", "February", "March", "April", "May", "
    June", "July", "August", "September", "October", "November", "December"};
32 int DayOfYear::daysInMonth[12] = {31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31};
33
34 int main() {

```

```

35     int dayOfYear;

37     // Loop until a valid day is entered
38     do {
39         cout << "Enter a day of the year (1-365): ";
40         cin >> dayOfYear;

42         if (dayOfYear < 1 || dayOfYear > 365) {
43             cout << "Day out of range! Please try again." << endl;
44         }
45     } while (dayOfYear < 1 || dayOfYear > 365);

47     DayOfYear day(dayOfYear);
48     day.print();

50     return 0;
51 }

```

## Assignment 12

Contributor: Ngo Thanh Trung - 1677469

### Java

#### 8.3

### 3. Carpet Calculator

The Westfield Carpet Company has asked you to write an application that calculates the price of carpeting for rectangular rooms. To calculate the price, you multiply the area of the floor (width times length) by the price per square foot of carpet. For example, the area of floor that is 12 feet long and 10 feet wide is 120 square feet. To cover that floor with carpet that costs \$8 per square foot would cost \$960. ( $12 \times 10 \times 8 = 960$ .)

First, you should create a class named `RoomDimension` that has two fields: one for the length of the room and one for the width. The `RoomDimension` class should have a method that returns the area of the room. (The area of the room is the room's length multiplied by the room's width.)

Next you should create a `RoomCarpet` class that has a `RoomDimension` object as a field. It should also have a field for the cost of the carpet per square foot. The `RoomCarpet` class should have a method that returns the total cost of the carpet.

Figure 8-21 is a UML diagram that shows possible class designs and the relationships among the classes. Once you have written these classes, use them in an application that asks the user to enter the dimensions of a room and the price per square foot of the desired carpeting. The application should display the total cost of the carpet.

Figure 20: 8.3 Task Requirement

```

1 package carpetCalculator.Code;
2 import java.util.Scanner;

4 public class CarpetCalculator {

```

```

5  public static void main(String[] args) {
6      Scanner sc = new Scanner(System.in);

8      System.out.print("Enter the length of the room (m): ");
9      double length = sc.nextDouble();
10     System.out.print("Enter the width of the room (m): ");
11     double width = sc.nextDouble();

13     RoomDimension myRoom = new RoomDimension(length, width);
14     System.out.println("Room entered area (m^2): " + myRoom.getRoomArea());

16     System.out.print("Enter the price per square ( ): ");
17     double pricePerSquare = sc.nextDouble();

19     RoomCarpet myCarpet = new RoomCarpet(myRoom, pricePerSquare);
20     System.out.println("Price for " + myRoom.getRoomArea() + " room area: " +
21         myCarpet.getTotalCost() + " ");
22 }

```

42: CarpetCalculator.java

```

1  package carpetCalculator.Code;

3  public class RoomCarpet {
4      private RoomDimension roomDimension;
5      private double costPerSqF = 0;

7      public RoomCarpet(RoomDimension roomDimension, double costPerSqF) {
8          this.roomDimension = roomDimension;
9          if (costPerSqF > 0) {
10             this.costPerSqF = costPerSqF;
11         }
12     }

14     public double getTotalCost() {
15         return costPerSqF * roomDimension.getRoomArea();
16     }
17 }

```

### 8. Parking Ticket Simulator

For this assignment you will design a set of classes that work together to simulate a police officer issuing a parking ticket. You should design the following classes:

- **The `ParkedCar` Class:** This class should simulate a parked car. The class's responsibilities are as follows:
  - To know the car's make, model, color, license number, and the number of minutes that the car has been parked.
- **The `ParkingMeter` Class:** This class should simulate a parking meter. The class's only responsibility is as follows:
  - To know the number of minutes of parking time that has been purchased.

#### Programming Challenges

- **The `ParkingTicket` Class:** This class should simulate a parking ticket. The class's responsibilities are as follows:
  - To report the make, model, color, and license number of the illegally parked car
  - To report the amount of the fine, which is \$25 for the first hour or part of an hour that the car is illegally parked, plus \$10 for every additional hour or part of an hour that the car is illegally parked
  - To report the name and badge number of the police officer issuing the ticket
- **The `PoliceOfficer` Class:** This class should simulate a police officer inspecting parked cars. The class's responsibilities are as follows:
  - To know the police officer's name and badge number
  - To examine a `ParkedCar` object and a `ParkingMeter` object, and determine whether the car's time has expired
  - To issue a parking ticket (generate a `ParkingTicket` object) if the car's time has expired

Write a program that demonstrates how these classes collaborate.

Figure 22: 8.8 Task Requirement

```

1 package Code;

3 public class ParkedCar {
4     private String make;
5     private String model;
6     private String color;
7     private String licenseNumber;
8     private int parkedMinutes;

10    public ParkedCar(String make, String model, String color, String licenseNumber
        , int parkedMinutes) {

```

```

11         this.make = make;
12         this.model = model;
13         this.color = color;
14         this.licenseNumber = licenseNumber;
15         if (parkedMinutes >= 0) {
16             this.parkedMinutes = parkedMinutes;
17         } else {
18             this.parkedMinutes = 0;
19         }

### 13. Carpet Calculator

The Westfield Carpet Company has asked you to write an application that calculates the price of carpeting for rectangular rooms. To calculate the price, you multiply the area of the floor (width times length) by the price per square foot of carpet. For example, the area of floor that is 12 feet long and 10 feet wide is 120 square feet. To cover that floor with carpet that costs \$8 per square foot would cost \$960. ( $12 \times 10 \times 8 = 960$ .)

First, you should create a class named `RoomDimension` that has two `FeetInches` objects as attributes: one for the length of the room and one for the width. (You should use the version of the `FeetInches` class that you created in Programming Challenge 11 with the addition of a `multiply` member function. You can use this function to calculate the area of the room.) The `RoomDimension` class should have a member function that returns the area of the room as a `FeetInches` object.

Next, you should create a `RoomCarpet` class that has a `RoomDimension` object as an attribute. It should also have an attribute for the cost of the carpet per square foot. The `RoomCarpet` class should have a member function that returns the total cost of the carpet.

Once you have written these classes, use them in an application that asks the user to enter the dimensions of a room and the price per square foot of the desired carpeting. The application should display the total cost of the carpet.

#### 14. Parking Ticket Simulator

For this assignment you will design a set of classes that work together to simulate a police officer issuing a parking ticket. The classes you should design are:

- **The `ParkedCar` Class:** This class should simulate a parked car. The class's responsibilities are:
  - To know the car's make, model, color, license number, and the number of minutes that the car has been parked
- **The `ParkingMeter` Class:** This class should simulate a parking meter. The class's only responsibility is:
  - To know the number of minutes of parking time that has been purchased

#### Review Questions and Exercises

- **The `ParkingTicket` Class:** This class should simulate a parking ticket. The class's responsibilities are:
  - To report the make, model, color, and license number of the illegally parked car
  - To report the amount of the fine, which is \$25 for the first hour or part of an hour that the car is illegally parked, plus \$10 for every additional hour or part of an hour that the car is illegally parked
  - To report the name and badge number of the police officer issuing the ticket
- **The `PoliceOfficer` Class:** This class should simulate a police officer inspecting parked cars. The class's responsibilities are:
  - To know the police officer's name and badge number
  - To examine a `ParkedCar` object and a `ParkingMeter` object, and determine whether the car's time has expired
  - To issue a parking ticket (generate a `ParkingTicket` object) if the car's time has expired

Write a program that demonstrates how these classes collaborate.

28     return 0;
29 }
```

#### 63: main.cpp

The image shows a Visual Studio Code editor window with a C++ project. The left sidebar displays the file explorer with the following files: `ParkedCar.h`, `ParkingMeter.cpp`, `ParkingMeter.h`, `ParkingTicket.cpp`, `ParkingTicket.h`, `PoliceOfficer.cpp`, and `PoliceOfficer.h`. Below these are folders for `Result` and `out`, and a section for `External Libraries`.

The main editor area shows the `PoliceOfficer.h` file with the following code:

```
10 class PoliceOfficer {
11 private:
12     string name;
13     string badgeNumber;
14
15 public:
16     PoliceOfficer(const string& off
17     ParkingTicket* inspectCar(const
18 };
19
```

The bottom panel shows the `Terminal` with the following output:

```
→ 14.14 Parking Ticket Simulator git:(master) × g++ -o out Code/Main.cpp Code/ParkedCar.cpp Code/Pa
→ 14.14 Parking Ticket Simulator git:(master) × ./out
Checking carValid:
No ticket issued. The car is legally parked.

Checking carFined:
Parking Ticket:
Car Make: Toyota
Car Model: Corona
Car Color: White
License Number: ABC123
Fine Amount: $35
Issued By: Officer Ngo Trung (Badge 342FHCB7)
→ 14.14 Parking Ticket Simulator git:(master) ×
```
